

The regimes differ at the TPM level ( $z = 35$ ); their  $\Phi$  landscapes cannot be distinguished above sampling noise at current volume

a  $\Sigma\phi$  per state under each TPM (full data)

b Same-regime reproducibility  $\approx$  cross-regime agreement

c  $\Sigma\phi(0000)$ : half-sample scatter swallows the regime gaps (dots = halves,  $\blacklozenge$  = full)
